The final version was published in July 15, 2010 (web link: http://www.salute.gov.it/imgs/C_17_pubblicazioni_1301_allegato.pdf).

Authorized by the Ministry of Health and Istituto Superiore di Sanità, National AIDS Centre. In collaboration with the National AIDS Commission and the Conference of Associations for the War Against AIDS, Ministry of Health, and with the Italian Society of Infectious and Tropical Diseases (SIMIT).

INTRODUCTION

This short version complies with the intention expressed in the methodological introduction to the full text *Italian Guidelines for the use of antiretroviral drugs and the diagnostic-clinical management of people with HIV-1 infection*. By definition, this version should not be considered completely exhaustive with respect to the full text version of the Guidelines, that are available at web site: http://www.salute.gov.it/imgs/C_17_pubblicazioni_1301_allegato.pdf.

Adriano Lazzarin, MD

San Raffaele Scientific Institute

Department of Infectious Diseases

Via Stamira D'Ancona 20 - 20127 Milano, Italy

E-mail: adriano.lazzarin@hsr.it

The aim of this version is simply to render certain concepts expressed in the document more usable, by specific circulation in booklet form, inviting the reader to refer to the extended version for further information and full details.

It was decided not to discuss *in toto* in this version certain fundamental parts of the extended versions such as the populations requiring special attention (elderly, women, immigrants, children), the conditions requiring special attention (drug and/or alcohol addiction, detention) or the situations requiring special attention (transplants).

For all these populations, conditions or situations, it should be referred at the full text version of the Guidelines.

Lastly, it was decided to refer the reader to the extended version for all bibliographic citations, except for the essential references cited at the end of this version.

С	Optional.			

TABLE 1 - Degree of re	commendation and le	vel of evidence
------------------------	---------------------	-----------------

	Level of evidence				
LEVEL I	The data are collated from at least one controlled, randomized study with sufficient potency or from s meta-analysis of controlled studies.				
LEVEL II	The data are collated from non-randomized studies or from cohort observational studies.				
LEVEL III	Recommendation based on case reviews or agreement among experts.				

PATIENT ASSESSMENT AND PREPARATION

The initiation of combination antiretroviral therapy (cART) should be considered a crucial moment in the management of HIV infection which requires:

- particular competency of the attending physician;
- comprehension and agreement on the part of the patient.

Physician-patient communication and the quality of their relationship can influence acceptance of this new phase. In particular, the capacity to establish a rapport of trust in the relationship conditions the willingness of the patient to accept and agree to the therapeutic prescription.

It is thus fundamental to assess the individual's degree of receptiveness, which depends on social, cognitive and emotional variables, and affects the capacity to understand the the information provided. It is emphasized that information skills depend not only on talking skills but also on the capacity to listen and understand.

Recommendations [AIII]:

- Offer the patient an interview in private.
- Guarantee the time necessary for comprehension, listening to and answering the patients' questions.

- Explain in detail why it is important and/or necessary to commence HAART.
- Inform the patient of the treatment options with a discussion of the benefits and risks of each approach.

VIRO-IMMUNOLOGICAL DIAGNOSTICS

The diagnosis of chronic HIV-1 infection is defined by the presence of HIV-1 antibodies, confirmed by immunoblotting.

The plasma HIV-RNA concentration (viremia or viral load) is used as a surrogate marker and serves to forecast the risk of clinical progression of the infection (prognostic marker) and assess the degree of the therapeutic response (efficacy marker). The principal objective of combination antiretroviral therapy in all patients is a reduction in viremia to undetectable levels (undetectability), and the maintenance of virological suppression for as long as possible [AII]. To date, the guidelines suggest using a limit value of greater than 50 copies/mL as the criteria for virological failure assessment [AI].

The use of resistance tests is currently recommended both for the choice of the first line therapy [AII] and for the choice of alternative therapy in the case of virological failure [AI]. The use of genotype assays is preferable to phenotype assays. Resistance assays should be interpreted with the use of viral genetic sequences with management algorithms (virological interpretation). Ideally, resistance assays should be interpreted by clinician with experience in utilizing additional parameters in the assessment, such as previous resistance tests, immunovirological and therapeutic data (virological and clinical interpretation). The best interpretation can be obtained in the latter conditions [AII]. An additional assessment with phenotype tests may prove useful for patients with complex resistance situations [BIII].

The data available to date indicate the utility of genotype or phenotype test for assessment of the prevalent viral strain for the purpose of using CCR5 antagonists [AII]. The simplicity of performance, lower costs, and the reliability of the test favour the genotypic assay [BII]. an essential prognostic marker. The CD4 count determines the indication for initiation of antiretroviral therapy as well as the initiation or suspension of prophylaxis of opportunistic infections [AI].

The CD4+ count should be repeated 1 month after commencing antiretroviral therapy and, subsequently every 3-4 months in the stable phase. In patients with unsatisfactory immunological recovery (<50-150 cells/ μ L per year), immunological monitoring should be more frequent (2/3 months) [BI].

The percentage CD4+ count must be assessed together with the total CD4+ count as an immune system function marker (CD4+ percentages below 14% are associated with an increased risk of opportunistic infections, approximately equivalent to a CD4+ count of <20 cells/ L) [AII].

Quantification of the CD4+ lymphocyte count is

WHEN TO START

TABLE 2 - When to start in patients with acute infection.

Condition	Recommendation for treatment	Strength/evidence		
Acute infection or recent seroconversion	Not recommended			
Acute infection with severe symptomatology	Highly recommended*	[AII]		
*If therapy is initiated, inclusion in a controlled clinical study is recommended where possible [BIII]				

Clinical condition	<i>Lymphocyte T</i> <i>CD4+ count</i>	Recommendation for treatment	Strength/evidence
AIDS	Any value	Highly recommended	[AI]
HIV-related diseases (group B of 1993 CDC definition)	Any value	Highly recommended	[AII]
Pregnancy	Any value	Highly recommended	[AI]
HIV-associated nephropathy (HIVAN)	Any value	Highly recommended	[AII]
Non AIDS-definining cancers	Any value	Highly recommended	[AII]
HIV-associate neurocognitive disorders (HAND)	Any value	Highly recommended	[AII]
Chronic HBV hepatitis requiring treat- ment*	Any value	Highly recommended with agents active against both HIV and HBV	[AII]
Elevated risk of secondary HIV trans- mission	Any value	Moderately recommended only in the case of a motivated patient	[BII]

 TABLE 3 - When to start in patients with chronic infection.

_

Clinical condition	Lymphocyte T CD4+ count	Recommendation for treatment	Strength/evidence	
Asymptomatic	mptomatic CD4+: ≤201-350 cells/µL Highly recommended		[AII]	
Asymptomatic	CD4+: 351-500 cells/µL	Moderately recommended in all patients Highly recommended in the presence of: a) HIV-RNA >100.000 copies/mL b) decrease in CD4+ >100 cells/ L per year c) age >50 years d) chronic hepatitis from HCV Moderately recommended in the case of: e) elevated cardiovascular risk: diabetes mellitus or previous cardiovascular event,	[BII] [AII] [AII] [AII] [AII] [BIII]	
	or elevated risk in the next 10 years (esti- mate with <i>Framingham</i> algorithm)			
Asymptomatic	CD4+ >500 cells/µL	Not recommended, except in cases of a highly motivated patient and/or in the presence of the factors indicated above at items a), b), c), d), e), where it is optional.	[CII]	
*In cases in which there is indication of HBV treatment by nucleotide/nucleoside analogues.				

 TABLE 4 - Timing of initiation of antiretroviral therapy in patients with AIDS or non-AIDS defining neoplasias (treatment Highly recommended [AI]).

Clinical condition	Timing of commencement of antiretroviral therapy	Strength/evidence (referred to the timing of commencement of arv therapy)
- Multifocal progressive leukoencephalopathy - HIV encephalopathy - Wasting syndrome - Enteritis from <i>Cryptosporidium</i> or <i>Microsporidia</i>	Immediate initiation highly recommended	[AII]
Pneumonia from <i>P. jiroveci</i>	Highly recommended initiation within 2 weeks of diagnosis	[AI]
Pulmonary tuberculosis	Highly recommended initiation within 3 months of anti-tubercular therapy	[AI]
Tubercular meningitis	Moderately recommended initiation after 2 months of 4 drug anti-tubercular therapy	[BI]
Cryptococcal meningitis	Highly recommended initiation upon completion of induction therapy for opportunistic infection	[AI]
Disease from atypical mycobacteria	Optional, where possible, initiation within 4 weeks of treatment for mycobacteriosis	[CIII]
CMV Disease	Optional, where possible, initiation upon completion of induction therapy for opportunistic infection	[CIII]
Patients with neoplasia	Highly recommended immediate initiation and, in all cases recommended prior to initiation of chemotherapy	[AII]

WHAT TO START WITH

The choice of initial therapy in patients with HIV must be tailored to:

- 1. Available data on the characteristics of the different agents and drug combinations (virological and immunological efficacy, conformulation/convenience, toxicity and tolerability, genetic barrier, prior clinical use).
- 2. Factors regarding the overall clinical status, genetic factors, and characteristics of the patient including:
 - Comorbidities (cardiovascular disease, hepatic, renal disease, neuro-cognitive disor-

ders, psychiatric illness, concurrent infections and/or conditions such as drug abuse/dependence, etc.);

- Potential adverse effects of the drugs used;
- Potential drug-drug interactions;
- Current or pregnancy potential;
- Genotype resistance test;
- Likelihood of adherence to treatment;
- Acceptability of regimen (number of pills, number of administrations, assumption modality);
- CD4+ lymphocytes count, if use of nevirapine is considered;
- HLA-B 5701, if use of abacavir is considered.

 TABLE 5 - Conditions for classification of drugs and combinations.

Conditions for classification of drug/combination

Drug/combination satisfying the majority of the following conditions: it is considered "*standard of care*"; in at least one randomized study it has shown to be at miniumum non inferior to "*standard of care*"; is compact/ convenient; it has a favourable toxicity and tolerability profile; it has demonstrable extensive clinical use.

Drug/combination which does not satisfy all the first choice criteria but which may represent, in specific cases, the best choice for a given patient (profiles of toxicity, pharmacological interactions with concomitant treatments).

Drug/combination considered efficacious, in cases where the patient does not tolerate or is unable to take first choice or alternative drugs/associations.

To date, data in the scientific literature reports, almost exclusively, the results obtained with combination regimens consisting of: a backbone of nucleos(t)ides (NRTI) and a base of a third drug from another class. Indications for the choice of drugs constituting the backbone may be determined on the basis of available coformulations rather than the single drug.

To date, data in the scientific literature reports, almost exclusively, the results obtained with combination regimens consisting of: a *backbone* of nucleos(t)ides (NRTI) and a *base* of a third drug from another class. Indications for the choice of drugs constituting the *backbone* may be determined on the basis of available coformulations rather than the single drug.

Choices	Pharmacological association [Strength/evidence]	Comment
First Choice	TDF/FTC* [AI]	Superior to ZDV/3TC; co-formulated; QD.
	TDF/3TC* [BI]	Only non-inferior to d4T/3TC, greater risk of resistances at failure compared to TDF/FTC (but not by direct comparison); non co-formulated; QD.
	ABC/3TC**[BI]	Only non-inferior to ZDV/3TC; inferior to TDF/FTC in presence of elevated viral loads; in patients with viremia greater than 100,000 copies/mL it must not be used in combination with ATV/r or EFV, but only with LPV/r; lack of data on association with DRV/r and RAL; higher CV risk; co-formulated; QD.
Alternative	AZT/3TC [BI]	Less effective; greater toxicity; lower genetic barrier; lack of data on asso- ciation with DRV/r, ATV/r and RAL; co-formulated; non QD.

 TABLE 6 - Backbone nucleos(t)ide. First choice and alternatives.

•	Choices	Pharmacological association [Strength/evidence]	Comment
	Acceptable	ddI/3TC or FTC*** [CI]	ddI/3TC/EFV non-inferior to ZDV/3TC/EFV; greater toxicity than ddI, ab- sorption significantly determined by food; non co-formulated; QD.

*Tenofovir should not be used in patients with renal insufficiency.

**Abacavir can only be used in HLA-B*5701 negative patients (screening recommended [AI]) and clinical HSR surveillance must be maintained in these patients; use with care in patients at elevated risk of cardiovascular disease (*Framingham risk score* > 20%): even though observational data on increased cardiovascular risk with ABC not consistent and the biological mechanism insufficiently clarified; do not initiate concomitant treatment with nevirapine due to augmented risk of hypersensitivity reactions (HSR).

***Didanosine + FTC/3TC only in association with EFV; with ATV excess of early virological failures; long-term mitochondrial toxicity (pancreatitis, peripheral neuropathy, lactic acidosis), hepatic and endothelial (excess of myocardial infarction, non cirrhotic portal hypertension); not indicated in conjunction with ribavirin (see HIV/HCV co-infection chapter).

TABLE 7 - Third drug, first choice.

In regards to choice of class for the third agent, consideration should be given to long-term efficacy data, the genetic barrier to resistance and the long-term sequencing strategy. Choices Drug [Strength/ evidence] Comment EFV* (600 mg) [AI] Standard of care in the majority of randomized clinical studies in which it has consistently shown equivalence or superiority; neuro-psychiatric disturbances in the first 12 weeks administration; QD. Elevated tolerability. Non-inferior to EFV; non-inferior to LPV/r with lower ATV/r (300/100 mg QD) [AI] gastrointestinal toxicity and dyslipidaemia. Lack of data on the association with ZDV/3TC; hyperbilirubinaemia; QD. NVP** (400 mg) [BI] Criterion of non inferiority to EFV not reached; non-inferior to ATV/r (48 weeks) but greater toxicity; best lipid profile with respect to ATV/r; equivalent to LPV/r (>48 weeks) but greater toxicity. Lack of data on the association with ABC/3TC. BID; QD optional (not authorized in Italy). First Choice DRV/r (800/100 mg OD) [BI] Limited use in naïve patients. Non-inferiority demonstrated only with respect to LPV/r: lack of comparative studies with EFV or ATV/r. Lower gastrointestinal toxicity and dyslipidaemia than LPV/r. Lack of data on the association with ABC/3TC and ZDV/3TC. LPV/r*** (800/200 mg QD or Inferior to EFV at 96 weeks. Standard of care in the majority of comparati-400/100 BID) [BI] ve studies with other PIs; sole co-formulated PI; greater toxicity; 200 mg of RTV; greater dyslipidaemia and gastrointestinal disturbances than DRV/r and ATV/r; higher number of pills; BID (QD non-inferior to BID but only 48 weeks; QD inferior to DRV/r QD). RAL (400 mg BID) [BI] Limited use in naïve patients; non-inferior to EFV with fewer adverse events and dyslipidaemia; Lack of data on the association with ABC/3TC and ZDV/3TC; BID. *EFV must not be used during first trimester of pregnancy, in women planning pregnancy or who may become pregnant due to lack of contraceptive use.

*EFV must not be used during first trimester of pregnancy, in women planning pregnancy or who may become pregnant due to lack of contraceptive use. **NVP must not be used in women with CD4+ >250 cells/µL or in men with CD4+ >400 cells/µL (higher risk of hepatotoxicity and/or cutaneous *rash*); in the first two weeks of therapy utilize the induction dose 200 mg/day. Some pilot studies indicate excess early virological failure with use of TDF+3TC+NVP QD: this combination should therefore be avoided, with the TDF/FTC+NVP combination, both QD and BID were found efficacious in randomized studies. Use with care in patients with hepatic viral co-infection.

***LPV/r 400/100 BID is the first choice therapy in pregnant women.

Choices	Drug [Strength/ evidence]	Comment	
Alternative	FPV/r* (700/100 mg BID) [BI]	Non-inferior to LPV/r BID at 96 weeks with same toxicity profile; BID, 200 mg RTV and higher number of pills; QD not authorized in Italy.	
	SQV/r (1000/100 mg BID) [BI]	Non-inferior to LPV/r (but less hypertriglycerideamia), but with only 48 weeks follow-up; 200 mg RTV; higher number of pills; BID.	
Acceptable	ATV** (400 mg QD) [CI]	Non-inferiority study with small sample size does not confirm non-inferio- rity to ATV/r at 96 weeks; greater virological failures; studied only in asso- ciation with d4T+3TC.	
	Maraviroc*** [CI]	Non-inferior to EFV only in one post-hoc analysis; BID; studied only with AZT+3TC.	
*FPV/r 1400/200 mg QD [BI]) 48 week studies compared with NFV, daily dosing not authorized in Italy; FPV/r 1400/100 mg QD [BI]) small study, dosing not			

TABLE 8 - Third drug, alternative, acceptable choices

*FPV/r 1400/200 mg QD [BI]) 48 week studies compared with NFV, daily dosing not authorized in Italy; FPV/r 1400/100 mg QD [BI]) small study, dosing not authorized in Italy.

**ATV without ritonavir not authorized in Italy; not to be used in any case without ritonavir booster when in concomitant use with tenofovir (except where plasma levels can be verified by TDM, see specific chapter) and/or efavirenz. The panel has decided to await new data before making a definitive recommendation.

***Maraviroc not registered in Italy for first line use. In naïve patients it demonstrated non-inferiority at 96 weeks against efavirenz in only one post-hoc analysis. The agent was studied exclusively in association with AZT+3TC at a dosage of 300 mg BID. Good efficacy is to be expected with a non-thymidine analogue backbone. Nevertheless, the panel has decided to await new data before making a definitive recommendation.

 TABLE 9 - Comparison of virological and immunological efficacy, convenience and genetic barrier of different antiretroviral regimens used in the treatment of naïve patients (first and alternative choice).

	NUCLEOS(T)IDIC BACKBONE						
Rank	Virological efficacy	Immunological efficacy	Compactness/convenience (number of pills and administrations, co-formulation)	Extensive clinical use	Genetic barrier (lower frequency of resistance at failure)		
1	TDF/FTC TDF+3TC	TDF/FTC TDF+3TC ABC/3TC	TDF/FTC ABC/3TC	TDF/FTC TDF+3TC ABC/3TC AZT/3TC	TDF/FTC ABC/3TC

HOW TO CONTINUE: SIMPLIFICATION

Therapeutic simplification involves the modification of at least one drug in the regimen and is intended to improve quality of life by increasing tolerability, reducing number of pills/administrations, and reducing pharmacological interactions. By improving adherence, simplification also intends to reduce the risk of therapeutic failure. Reduced medium to long-term toxicities is a possible indication for simplification of therapeutic regimens. This section only considers simplification in conditions of virological suppression (HIV-RNA <50 copies/mL).

Indications for simplification

- Documented toxicity.
- Presence of side-effects.
- Planned pregnancy.
- Desire to simplify therapy.
- Current regimen no longer recommended.
- Prevention of long-term toxicity (*pre-emptive switch*).
- Current therapy may worsen co-morbidities or clinical manifestations linked with aging.
- Interactions with other drugs.
- Indication to treat other infections (TB, HBV, HCV, etc.).

Simplification strategies in patients with stably suppressed viremia

- Intra-class simplification in the case of side-effects to single agents, including improvement dyslipidaemia and/or lipodystrophy.
- Simplification to once daily administration of NRTI or PI/r administered BID in order to improve adherence.
- Simplification from PI/r to EFV, NVP or RAL to prevent or improve metabolic toxicity and improve adherence (only in cases with no prior virological failure and full activity of NRTIs utilized).

- Simplification to monotherapy with PI/r (DRV/r and LPV/r with reintroduction of the 2 NRTIs in the case of rebound to low viremia) in the case of toxicity or reduced NRTI tolerability: only in selected patients with no history of virological failure, with undetectable viremia (<50 copies/mL) for at least 6 months, good immunological recovery and CD4+ nadir >100 cells/µL, on treatment with PI/r and without PI resistance mutations as determined prior to initiation of antiretroviral treatment. In all cases, close virological monitoring is required for early assessment of possible failure.
- Simplification from enfuvurtide to raltegravir for ease of administration and elimination of cutaneous side-effects in patients with no previous treatment experience with integrase inhibitors.

MANAGEMENT OF THERAPEUTIC FAILURE

Despite the efficacy of current antiretroviral treatment, a measurable proportion of patients experience therapeutic failure due to a suboptimal virological response (virological failure), unsatisfactory immunological response (immunological failure) and, to a lesser extent, clinical progression (clinical failure). Clinical failure is defined by the onset of HIV-related clinical events in patients on antiretroviral therapy for at least three months, after the exclusion of immune reconstitution syndrome. Immunological failure may be defined as a failure to recover and/or maintain (a normal?) CD4+ lymphocytes count, despite virological suppression. Virological failure is defined by lack of suppression of HIV viremia to values below 50 copies/mL of plasma HIV-RNA (undetectability) 24 weeks after treatment initiation or as a rise in viral replication (rebound), confirmed by two consecutive measurements in patients who had previously achieved complete viral suppression.

117

Condition	Recommendation
Patients with residual low-level viremia (1-49 co- pies/mL).	Documentation of residual low-level viremia no longer satisfies the cri- teria for diagnosis of virological failure. On the basis of the data availa- ble there is no indication for modification of the current regimen [AIII].
Patients with viral blips (50-1000 copies/mL), iso- lated, non consecutive, alternating with unde- tectable viral load measurements.	Investigate adherence, potential pharmacological interactions, consider possible variability in the HIV-RNA test. Modification of the antiretro- viral regimen is not necessary [AII].
Patients with viral blips (50-1000 copies/mL) per- sistent, consecutive, progressively rising, genoty- pe non determinable.	There is no clear guidance in the literature on the appropriate manage- ment of these patients, although active, persistent viral replication is evi- dent. It is reasonable to undertake genotyping and consider modification of the current antiretroviral regime [BII].
Patients with viremia >1000 copies/mL and ab- sence of mutations in the genotypic resistance test performed.	Investigate adherence, consider resumption of the same regimen moni- toring the virological response after 4 weeks and repeating genotype for early identification of emergence of resistant viral variants [BIII]. In pa- tients on unboosted protease inhibitor therapy, consider immediate in- troduction of low doses of ritonavir as a pharmacokinetic booster [BII].
Patients with viremia >1000 copies/mL and mu- tations in the genotype test performed.	Modify the current antiretroviral regime [AII].

TABLE 10 - Recommendations for accurate, early assessment of virological failure.

TABLE 11 - Useful considerations when deciding on a new antiretroviral regimen in patientswith virological failure.

In a patient with virological failure, a new antiretroviral regimen must include at least 2, preferably 3 fully active drugs [AII]. In the case of first failure, it is advisable to choose drugs from classes that have not been used before.

With standard tests, the most recent genotype may not detect certain archived mutations. All of the patient's previous genotypic and phenotypic assays must be taken into consideration (when deciding on the appropriate choice of a new regimen); even agents to which the patients has never been exposed may not be fully active.

Consider all potential negative pharmacological interactions with the new regimen; a drug never taken before is not always a fully active drug when included in a new therapeutic regimen.

In patients who do not have three fully active drugs available, consider that some antiretroviral drugs (e.g. NRTIs) can contribute to the efficacy of the new regimen with partial antiviral activity, albeit in the presence of resistance, while for other drugs (e.g.: enfuvirtide, NNRTIs, raltegravir) no partial antiviral activity has been demonstrated.

Certain factors are associated with a more favourable virological response, irrespective of the type of regimen used (e.g.: low-level viremia and elevated CD4+ at the time of regimen modification, use of a drug from a new class, increasing number of active drugs and, therefore, GSS and PSS).

TABLE 12 - Recommended sequential regimens as determined by failed first line therapy.

First regimen	Second regimen
2 NRTI + NNRTI	2 NRTI* + PI/r
2 NRTI + PI/r	2 NRTI* + PI/r*
2 NRTI + PI	2 NRTI* + PI/r*
3 NRTI	*1 NRTI + 1 PI/r + 1 NNRTI *2 NRTI + 1PI/r 1PI/r + 1 NNRTI - 1PI/r + 1 INI - 1 PI/r + 1 CCR5 inhibitor
* = Chosen on the basis of resistance assay.	

Situation	Choice				
Availability of at least 2 active drugs*	Change the regimen as soon as possible. If possible include high genetic barrier drugs in the regimes (new boosted protease inhibitors) in combination with other agents of different classes chosen on the basis of resistance test results.				
Availability of 1 active drug only*	The most fragile situation, the decision to modify antiretroviral therapy must take into account the immediate risk of clinical progression, the risks associated to main- tenance of the current regimen and the probability of virological success of the sub- sequent regime in the medium term. A maintenance regimen may be reasonable whi- le awaiting the availability of another active drug.				
Absence of active drugs	Determine the optimal maintenance regimen.				
*of all agents available, in the market or in early access protocols.					

TABLE 13 - Management of virological failures subsequent to the first and use of new classes of drugs.

ADHERENCE AND QUALITY OF LIFE

Optimal adherence to antiretroviral drugs must always be pursued in order to obtain and maintain both the viro-immunological and clinical success of treatment [AII]. In the clinical setting, the patient's self-reported adherence, if investigated with a non-judgemental, routinized and structured fashion, is the most suitable method to measure adherence and institute longitudinal monitoring for early identification of specific barriers to adherence [AII]. Other objective methods, such as assessment of antiretroviral refill dates, pill counts, and plasma drug concentration monitoring may be utilized as adjunctive information to assess patient adherence [BII]. Simplified antiretroviral dosing with fixed-dose combinations has been shown to promote adherence to the antiretroviral therapy [AI].

In the clinical setting, observation of non-adherence behaviour requires intervention strategies [AI]. Identification of the most appropriate intervention is based on the experience of the medical-nursing staff and is based on a "tailored" approach combining strategies related to the antiretroviral management with educational and behavioural approaches providing support to the patient [BI]. The improvement in quality of life related to health is a primary objective of antiretroviral therapy. It is therefore necessary to include the use of patient-centered strategies in the clinical care of the patient. Ongoing monitoring of patient-centered outcomes is recommended in clinical centres, with the same frequency as standard clinical examinations [AII].

PHARMACOLOGICAL MONITORING

Definition of TDM

Therapeutic monitoring of plasma drug concentrations (TDM - Therapeutic Drug Monitoring) is a useful adjunct for individualizing therapy, especially when utilzing agents with a clear correlation between concentration and therapeutic and/or toxic effect, a limited therapeutic margin and wide inter-individual pharmacokinetic variability.

Scenario	Strength/evidence
Significant alterations of gastroenteric, hepatic or renal function	[CIII]
Pregnancy	LPV/r, SQV/r [CIII]
Previous failures with resistant virus	PI with use of IQ [CII]
Concentration-correlated toxicity	IDV/r [BII], EFV [CII], ATV [CIII]
Non-conventional dosing schemes	[CIII]
Treatment adherence	[CIII]
Pharmacological interactions	[BIII]

TABLE 14 - Clinical scenarios of possible use of TDM.

Interactions

The management of pharmacological interactions is the clearest clinical indication for use of TDM [BIII]. Different antiretroviral drug types or classes (NNRTI, IP, MVC) are associated with significant pharmacological interaction as they are, to various extents, substrates, inhibitors or inducers of the P450 cytochrome (in particular the CYP3A4 isoenzyme, but also CYP2B6, CYP2C9, CYP2C19) and P glycoprotein. The N(t)RTI, ENF and RAL have differentiated metabolic profiles and therefore have limited or low potential for interaction. Refer to specific sites (*first of all* **www-hiv-druginteractions.org**) for an exhaustive discussion of information pertaining to management of pharmacological interactions.

TABLE 15 - Principles of TDM use in the management of pharmacological interactions.

NNRTI, PI and MVC have a higher risk of pharmacological interaction as substrates, inhibitors or inducers of the P450 cytochrome system and P glycoprotein.

N(t)RTI, ENF and RAL have limited or low potential for interaction.

The extent of a known interaction may be unpredictable in individual cases [CIII].

The sum of several simultaneous pharmacological interactions is often difficult to predict [CIII].

The extent of the interaction may have different specific weights and effects depending on the clinical variables of the single case [CIII].

A pharmacological interaction may be unpredictable and must be suspected in the case of unexpected clinical and therapeutic events [CIII].

PHARMACO-GENETICS

TABLE 16 - Principles of use of genetic testingfor the HLA-B*5701 allele.

Highly recommended before starting antiretroviral therapy containing ABC [AI].

In negative patients clinical monitoring is recommended in all cases within the first 6 weeks of treatment as the possibility of abacavir associated HSR cannot be completely excluded [CIII].

The test should be performed at baseline in all newly infected patients in order to register data in the patients' clinical records for future use [CIII].

NON-INFECTIOUS COMORBIDITY

General principles

The non-infectious pathologies associated with HIV infection are the most frequent symptomatic manifestations in HIV-infected persons on antiretroviral therapy.

These derive from the interaction of risk factors relative to host, virus, and drug [BII]. Their clinical relevance affects:

- prognosis [AI];
- choice or modification of the antiretroviral drugs [AII];
- multidisciplinary patient management [AIII].

These comorbidities manifest in progressive organ damage leading to end-stage organ failure:

- End-stage organ failure determines patient morbidity and mortality [BII].
- They may be diagnosed by functional or structural tests with the capacity to detect disease in the asymptomatic stage [BII].
- Multiple comorbidites are physiological during aging and HIV infection is associated with a process of premature aging the pathogenetic mechanisms of which are only partially understood.

Risk factors associated with HIV infection are related to genetic and environmental factors which, in turn, affect lifestyle.

The recognition and correction of deleterious lifestyle choices are the most effective interventions for prevention and treatment of non-infectious comorbidities.

Factors related to HIV infection include immunological damage (*immunodeficit* and immune deregulation) and by a state of systemic inflammation associated with accelerated the cellular and organ senescence.

Undetectable HIV viremia does not eliminate the excess risk associated with HIV disease. Coinfections (hepatitis viruses, herpes viruses, etc.) are additional risks for non-infectious pathology.

The increased risk of specific organ damage associated with cumulative or current antiretroviral exposure occurs through mechanisms which have not been fully elucidated.

The table below shows the main risk factors for non-infectious comorbidites associated with HIV infection considered in these guidelines [AIII].

TABLE 17 - Risk factors for non-infectious comorbidities associated with HIV infection.

Screening for non-infectious comorbidities associated with HIV infection

120

Screening for non-infectious comobidities is an integral part of comprehensive clinical assessment in all HIV infected patients [AII]. Screening

must be periodic and should be repeated, in all patients, before starting antiretroviral therapy or when changing antiretroviral management strategy [AIII].

DXA has the advantage of providing objective anth- ropometric measure- ments for the diagnosis of lipodystrophy [BIII]

Assessment of the risk of toxicity associated with antiretroviral drugs

There are short- and medium-term toxicities linked with the use of antiretroviral drugs. Continuous exposure to antiretroviral therapy reinforces the need for post-marketing pharmacological surveillance [BII]. HIV infection control through virological suppression is a required for reducing drug related toxicities [AI].

The principal toxicities attributable to different classes and single drugs, based on data from registration studies or significant cohort studies, are listed below.

 TABLE 19 - Principal toxicities attributable to different ARV classes and single drugs.

General principles of treatment of non-infectious comorbidities

 TABLE 20 - Principles of intervention for main modifiable factors.

Interventions	Principles
Smoking cessation	Identify the motivational aspects for discontinuing smoking The short-term benefits are: - monetary savings - increased perception of flavours - improved skin trophism - reduction of dyspnea.
-	\rightarrow

125

Interventions Principles		Principles
	Smoking cessation	The long-term benefits are: - prevention of chronic obstructive pulmonary disease (COPD) - coronary artery disease and stroke - lung cancer Instruments of proven utility for smoking cessation: - refer to specialist anti-smoking centres - nicotine substitute products
Diet Nutritional counselling: - Maintain the balance betwo - Moderate intake of saturato - Limit alcohol consumption - Reduce total fat intake to < - Consume many vegetables, - Introduce fish, poultry (no - Avoid alternating periods o Specialist nutritional interve		Nutritional counselling: - Maintain the balance between calorie input and energy consumption - Moderate intake of saturated fats, cholesterol and refined carbohydrates - Limit alcohol consumption to <20 gr/day for females and <30 gr/day for males - Reduce total fat intake to <30% and cholesterol intake to <300 mg/day - Consume many vegetables, fruit and fibre rich cereals - Introduce fish, poultry (no skin) and lean meat to the diet - Avoid alternating periods of strict diet and binges (so-called yo-yo dieting) Specialist nutritional intervention reserved for obese patients and those with wasting syndrome
	Physical therapy	An active lifestyle is fundamental to prevent and treat obesity, hypertension and diabetes. Regular aerobic activity (e.g. 30 minutes of sustained walking at least 5 days a week) is useful to reduce the accumulation of visceral fat, maintain muscular strength and prevent osteoporosis. It is necessary to verify that the physical activity undertaken satisfies cardio-fitness requirements (adequate duration, adequate increment of cardiac frequency)

 TABLE 21 - Identification and management of patients at high risk of cardiovascular disease.

Identification of patients with high cardiovascular risk through: 1. Estimation of the risk of cardiovascular disease (CVD) with risk prediction charts or algorithms 2. Individual clinical assessment

Prevention	Management
In the case of co-infection with Hepatitis C virus evaluate the possibility of treating this condition: treatment of Hepatitis C reduces the risk of "drug-induced liver injury" (DILI). Refer to the specific section of the guidelines for ma- nagement of these cases. In obese patients and those with metabolic syndrome, ul- trasonography to assess the presence of NAFLD. Computed tomography (CT) and magnetic resonance imaging (MRI) may be used for further diagnostics in selected cases. Modifying predisposing factors for NAFLD such as hypergly- caemia, dyslipidaemia, arterial hypertension, abdominal obe- sity, may reduce the evolution of liver disease and prevent drug-related hepatotoxicity. Among the modifiable predi- sposing factors consider HCV infection with genotype 3, which is associated with hepatic steatosis and an increased risk of drug-associated liver damage. In patients starting nevirapine: check liver enzymes at base- line, every two weeks for the first month, each month for the first three months, then every three months. Reassessment of current antiretroviral therapy: because li- ver damage - above all when linked with mitochondrial to- xicity - may be clinically silent, it is important to evaluate the possibility of substituting older generation NRTI if pre- sent in current therapy.	Exclude other causes of liver enzyme elevation, in particular alcohol abuse, presence of co-infections with hepatitis viru- ses and interruption of treatment with 3TC, FTC and TDF in patients with chronic hepatitis B. In the case of liver enzyme elevation, if the patient is sympto- matic with a clinical hepatitis or a concomitant rise in bili- rubin, immediately discontinue all current treatment. Upon normalization, consider the use of antiretroviral drugs with minimal hepatic toxicity. In the asymptomatic patient, consider suspension of the drug in all patients with liver enzyme elevation 5-10 times the nor- mal level. In the presence of both augmented liver enzyme elevation and of symptoms drug hypersensitivity reaction, suspend current treatment immediately. Re-administration of the sa- me therapy may prove fatal.

Prevention and management of patients at high risk of hepatic damage

Prevention and manage	gement of patients at	high risk of	bone disease
-----------------------	-----------------------	--------------	--------------

Prevention	Management
Lifestyles beneficial for the prevention and treatment of osteoporosis include: physical activity, daily consumption of 1 g of calcium and Vit D 800 UI/day with a weight loss and malabsorption prevention diet (BMI <18.5), smoking cessation and decreased alcohol consumption. A height loss of more than 3 cm suggests a diagnosis of vertebral fracture. The classic risk factors for osteoporosis include: hypogonadism, family history of fractures, BMI <19 kg/m ² , hypovitaminosis D, smoking, sedentary lifestyle, low impact fractures, advanced age, female gender, menopause and/or amenorrhea, habitual alcohol consumption of >3 units/day, steroids exposure for >3 months. Plasma levels of 25-OH vitamin D should be checked in all patients preferably in autumn and spring. Testing is not necessary in patients taking regular nutritional supplementation. Correct assessment of the bone structure cannot be separated from a study mineral metabolism.	one toxicity of tenofovir is expressed in particular in st 12 months of therapy, especially if used in associa- ith PI/r and in pre-treated subjects: in the case of alte- s in renal function and/or of bone metabolism, and in essence of valid, efficacious alternatives, it is advisable ss options for treatment modification. are no antiretroviral therapy simplification strategies ven efficacy in the prevention or treatment of osteo- s. For correction of hypovitaminosis D, cholecalciferol e administered: two consecutive oral administrations ,000 UI each, preferably in spring and autumn, follo- y a maintenance dose of oral cholecalciferol of 7,000 h week. case of hypovitaminosis, testing of plasma calcium, hate, alkaline phosphatase and PTH levels is indica- ways supplement with calcium in the case of low ali- ry intake.

Prevention and	management	of patients	at high risk	of lipodvstrophv
		-) r		

Prevention	Management
For all patients with HIV infection, collection of anthropo- metric data including BMI, waist circumference, objective evaluation of adipose tissue redistribution is indicated, pos- sibly with questionnaires.	Modification of antiretroviral therapy, replacing thymidine analogues, is the only measure proven to partially re-esta- blish subcutaneous fat, with an average increase in total fat in the limbs of up to 400-500 g/year. The option of NRTI-spa- ring regimes is also available.
	\rightarrow

_

>	Prevention	Management
*	Prevention A correct diet and physical activity can reduce the accumulation of visceral fat and lead to improvement in insulin sensitivity and blood lipids, especially in obesity associated with lipo-hypertrophy. This intervention may, however, exacerbate subcutaneous lipo-atrophy.	ManagementReplace d4T or ZDV with abacavir (ABC) or tenofovir (TDF).The potential risk of toxicity linked with the use of thesedrugs must be taken into consideration.Avoid use of stavudine (d4T) and of zidovudine (ZDV, AZT),or switch to other drugs as prevention.Consider Nucleoside Reverse Transcriptase Inhibitors(NRTI)-sparing regimens. Using these regimes may be associated with an increase risk of dyslipidaemia.There are no antiretroviral therapy switch strategies withproven efficacy in the treatment of lipo-hypertrophy.Surgical intervention to correct facial lipo-atrophy is not aesthetic surgery but repair of an iatrogenic injury. Indeed, these have a positive effect on the quality of life and on depression, reducing the stigma of HIV disclosure and infection"revealed" by recognition of the lipo-dystrophic phenomenon, and is a potential intervention to support adherence to antiretroviral therapy.The surgical approach may be undertaken either by autotransplant of adipose tissue (lipo-filling) or by treatment with synthetic fillers are preferable in patients with less severe lipo-atrophy and under 50 years of age, while non re-absorbable synthetic fillers is not recommended in the treatment of non facial lipo-atrophy.The use of medical therapies to improve lipo-atrophy has produced conflicting results. In particular, the use of thiazo-lidinediones such as rosiglitazone and pioglitazone did not result in a significant increase of adipose tissue but may exacerbate subcutaneous lipo-atrophy and insulin resistan-ce. Tesamorelin (growth hormone release factor), currently not authorized in Europe, has been shown to be efficacious in reduces visceral adipose tissue but may exacerbate subcutaneous lipo-atrophy.
		Surgical intervention to correct lipo-hypertrophy may be con- sidered for removal of localised lipomas and to correct buf- falo hump although the duration of the effect is variable [BIII].

Prevention and m	ianagement (of patients	at high risk	of kidney disease
------------------	--------------	-------------	--------------	-------------------

Prevention	Management
Assessment of glomerular function is performed with pre- diction algorithms which include serum creatinine level, age, sex, ethnic origin and anthropometric measurements. Calculation of creatinine clearance is necessary, as the se- rum creatinine value depends to a variable extent on extra- renal factors; further, the correlation between creatinine and glomerular filtratation is not linear.	In cases of Fanconi syndrome in tenofovir-treated patients, tenofovir must be discontinued immediately. In patients with estimated glomerular filtrate <50 mL/min dose adjustments should be performed where necessary. The need for treatment modification should be assessed every time GFR is below 60 ml/min and/or in the case of observation of proteinuria/ microhematuria.

127

~

*	Prevention	Management
	Measurement urine over 24 hours, while more tim-consu- ming, is more accurate and certainly preferable to use of the Modification of Diet in Renal Disease (MDRD), Cockcroft- Gault (CG), EPI-CKD formulae. Given the close connection between renal damage and car- diac damage, cardiovascular prevention interventions, with particular reference to hypertensive disease, appear effica- cious in the prevention of kidney disease as well.	In these cases, risk assessment for renal dysfunction is indi- cated, discontinue or change drug doses where indicated, and consider ultrasonography of the kidneys; in the case of hematuria, irrespective of the degree of proteinuria, consult a specialist nephrologist.

FIGURE 1 - Clinical management of renal failure (1a) and proteinuria (1b).

HIV-associated neuro-cognitive disorders

The clinical outcome and quality of life of people with HIV infection can be profoundly influenced by the presence of neuro-cognitive and/or psychiatric disorders, whether these are the consequence of HIV damage to the central nervous system (CNS) - defined in this case as *HIV-associated neuro-cognitive disorders* (HAND), attributable to other causes, or to the combination of the two.

HIV does not infect neurons directly, but the infection and consequent activation of CNS macrophages, the target cells in this tissue, can trigger a cascade of events, including the production of inflammatory, neurotoxic molecules leading to neuron dysfunction, degeneration and death.

The clinical equivalent of these events is represented by a neurocognitive disorder which, in more severe forms, manifests with a state of dementia (HAD, *HIV-associated dementia*). A classification of HAND was recently proposed on the basis of the severity of the deficit, as established by neuropsychological examination.

TABLE 22 - Classification of HIV-associated neurocognitive disorders (HAND).

	Alteration in ≥2 cognitive areas documented by np exam	Interference with daily life
Asymptomatic Neurocognitive Impairment (ANI)	Present	No
Mild Neurocognitive Deficit (MND)	Present	Mild
HIV-associated dementia (HAD)	Present	Severe

HAND: HIV-associated - Disorders; ANI: Asymptomatic Neurocognitive Impairment; MND: Mild Neurocognitive Disorder; HAD: HIV-Associated Dementia; NP Exam: Neuropsychological Examination

While the incidence of HAD fell after the introduction of combination antiretroviral therapy (cART), the general prevalence of neuro-cognitive disorders rose, likely due the increase over time of incident cases and the longer survival of HIV-infected individuals, and now affects 25%-50% of patients. HAND is associated with several risk factors, including:

- A CD4+ nadir <200 cells/µL;
- Age over 50 years;
- Co-infection with HCV, diabetes or insulin resistance.

HIV-infected patients have a high prevalence of a number of conditions/comorbidities that are independently associated with neurocognitive disorders *which may contribute to or totally explain the cognitive deficit, and confound a diagnosis of HAND*:

- Depression;

- Anxiety disturbances;
- Psychoses and other psychiatric disorders;
- Vascular and ischemic dementia;
- Alzheimer's disease;
- Opportunistic infections or CNS neoplasia;
- Metabolic encephalopathies;
- Hepatic cirrhosis;
- Co-infection with HCV;
- Current or previous history of drug abuse (cocaine, methamphetamine, opiates);
- Abuse of psychiatric drugs;
- Alcoholism;
- Prior concussive cranial trauma.

Diagnosis of HIV-associated neurocognitive disorders (HAND)

The diagnostic procedures recommended for the management of the patient with or at risk of HAND are reported below.

FIGURE 2 - Diagnostic algorithm for the diagnosis and treatment of HIV-associated neurocognitive disorders (HAND). Abbreviation legend - IHDS: International HIV Dementia Scale; MMSE: Mini Mental State Examination; IADL: Instrumental Activities of Daily Living; NP Exam: Neuropsychological Examination; MRI: Magnetic Resonance Imaging of the brain with contrast media. Notes on the algorithm: ¹To highlight difficulties in the execution of one or more of the following functions: plan and execute complex tasks; perform simple, timed, cognitive functions; maintain usual levels of attention; have good temporal-spatial orientation; maintain behaviour suitable to environmental circumstances; have good prospective memory or memory of activities or future plans; and to highlight shades of possible psychiatric symptomatology (e.g. symptoms of depression or anxiety). ²Patients with evident and/or documented neurocognitive alterations do not require screening tests and are direct candidates for NP exam. To enhance the diagnostic sensitivity of the MMSE some experts propose raising the classic cut-off from 24/30 to 28/30. ³In patients with symptoms not explained by neurocognitive alterations, specialist consultation is indicated for the diagnosis and treatment of possible psychiatric or psychological disorders. ⁴Include neurological examination and blood tests to exclude conditions/co-morbidities associated with non-HAND neuro-cognitive disorders. ⁵Risk factors: CD4+ nadir <200 cells/µL, age >50 years, HCV-Ab positivity, diabetes or insulin resistance. ⁶Examinations aims to distinguish HAND and exclude other pathologies. The CSF test is indicated principally to study HIV-RNA level (concomitant with evaluation of plasma viremia) and of drug resistance. ⁷To define drugs with elevated penetration and efficacy in the CNS, the use of *Central nervous system Penetration Effectiveness* - CPE Score (*Letendre S et al.*, CROI 2010) is recommended [see below].

Level	Examination(S)	Objective(S)	Population		
1a	Targeted history-taking*, neurological examination	Identification of patients with possible neurocognitive or psychiatric disorders	All [AIII]		
1b	IHDS, MMSE	Identification of patients with possible neurocognitive disorders.	All [AIII] or, where not practicable in all, at least in patients with 1 or more risk factors (Figure 1, note 5)

GRT: Ger	GRT: Genotypic Resistance Test. *See note 1 above. **See note 2 above.				

TABLE 23 - Diagnostic route to diagnosis of HIV associated neurocognitive disorders (HAND).

 TABLE 24 - Antiretroviral therapy in patients with mild neuro-cognitive disorders (MND)
 or HIV-associated dementia (HAD).

	Clinical scenario and possible biological basis	ARV Therapy*	
Not on ARV therapy, MND/HAD	Productive infection of CNS	ARV therapy with 3 drugs, all with elevated pene- tration and efficacy in the CNS, also taking into ac- count GRT in plasma and, if available, in CSF [AII]	
On ARV therapy with therapeutic failure, MND/HAD	 a) HIV RNA detectable in CSF with GRT comparable or different to plasma: productive infection of CNS due to to high viral replication in the CNS and/or re- sistance in the CNS and/or poor penetration/ efficacy of ART in CNS. b) HIV-RNA not detectable in CSF: possible low-level HIV replication in CSF or presence of chronic CNS damage 	Modification of ARV therapy on the basis of the GRT on plasma (a, b) and on CSF (a), using more effec- tive or at least equivalent o current therapy in terms of CNS penetration and efficacy.	
On ARV therapy with viremia suppressed, MND/HAD	 a) HIV-RNA detectable in CSF: productive infection of CNS due to compartmentalised viral replication and/or resistance in CSF and/or poor penetration/ ef- ficacy of ART in CNS. b) HIV-RNA not measurable in CSF: possible low-level HIV replication or presence of chronic damage to CNS. 	Modification of ARV therapy on the basis of the GRT on CSF and previous resistance tests on plasma, with preference for agents with elevated CNS penetration and efficacy (a) [AII]. Strengthening therapy by ad- dition of one or more drugs with elevated CNS pe- netration and efficacy (a, b) [BIII].	
*For drugs with elevated CNS penetration and efficacy, refer to Table 3 on the CPE score (see full version of the Guidelines), in which the drugs with most			

*For drugs with elevated CNS penetration and efficacy, refer to Table 3 on the CPE score (see full version of the Guidelines), in which the drugs with mos elevated penetration and efficacy are assigned a higher score.

Prevention of symptomatic HIV-associated neuro-cognitive disorders (HAND) (MND, HAD)

In the absence of MND or HAD it is important to identify the patients most at risk of developing symptomatic neuro-cognitive impairment in the future and to employ effective strategies for its' prevention.

In both patients with ANI, and patients without neuro-cognitive alterations, but with risk factors

(CD4+ nadir <200 cells/µL, age >50 years, co-infection with HCV, diabetes or insulin resistance), careful neuro-cognitive monitoring is indicated (with NP and IADL exam every 12 months to evaluate eventual evolution towards MND) [AII]; the use of drugs with elevated CNS penetration and efficacy both in cases of with ≥2 risk factors for HAND development [AII], and in patients with no compromise and ≥2 risk factors is suggested[CIII].

 TABLE 25 - Monitoring the efficacy of antiretroviral therapy in HIV-Associated neuro-cognitive disorders (HAND).

Level	Scenario	Objective	Examinations
1	Starting or changing cART, HAND	Initial evaluation of the efficacy of the (new) therapy on the neuro-co- gnitive impairment	After 6 months: NP exam [AII]
2°	cART monitoring: HAND with reco- very of neuro-cognitive impairment	Monitor the efficacy of cART on the neuro-cognitive impairment	Every 12 months: NP exam [AII]
2b	cART monitoring: HAND with no re- covery or worsening of neuro-cogni- tive impairment	Search for virological escape in the CNS Exclusion of other causes of neuro- cognitive impairment	Neurological examination [AII] MRI of the brain [AII] CSF examination (HAD and MND) and tests to exclude other disor- ders [AII], HIV RNA [AII], GRT [AII] After 6 months: NP exam [AII]

Tumours

Treatment for HIV-associated tumours is very complex and must be the product of a strategic and operative agreement between the oncologist and the infectious disease specialist.

This section is intended to focus only on certain aspects of this complex problem, mainly addressing the general principles of timing, choice and management of antiretroviral therapy in the HIV patient with malignancies.

Thus, this discussion must not be considered an exhaustive review of the complex issue of tumour management in the HIV-infected patient, a scenario which requires specific study and recommendations in clinical, diagnostic and therapeutic domains.

HIV-positive patients must regularly undergo screening for solid cancers, in particular for breast cancer, colorectal neoplasia and prostate carcinoma, whose cost-efficacy is largely documented in the general population [AI].

Initiation of HAART is, in general, recommended

concomitant to the anti-neoplastic treatment [AII], with the possible exception of patients with non-AIDS defining cancers, elevated CD4+ levels, and possible drug interactions associated with severe with toxicity [BIII]. HAART is recommended in all patients treated with highly immuno-suppressive therapies.

In candidate patients for concomitant treatment with HAART and chemotherapy (CT), consideration of possible drug-drug interactions and cumulative toxicity must guide and orient the choice of antiretroviral therapy.

The potential interactions between antiretrovirals and chemotherapy should be considered before the a therapeutic regimen is chosen [AIII], with reference to the most up to date data in the literature (see http://www.hiv-druginteractions. org).

The use of antiretroviral TDM is recommended to check for interactions and accumulated toxicities [CIII].

INFECTIVE COMORBIDITY

Infection by hepatitis viruses

When to start antiretroviral therapy

Patients with hepatitis virus co-infection -Maintenance of CD4+ count over 500 cells/µL and HIV viral suppression are recommended [BII]. Patients with HCV co-infection - With a CD4+ count >500 cells/µl, starting antiretroviral therapy is highly recommended [AII]. In patients with indications for anti-HCV therapy with interferon and ribavirin and with CD4+ <500 cells/µL or with unstable HIV disease (indicated by HIV-RNA >100.000 copies/mL and/or decline of the CD4+ >100 cells/ L in the last year) anti-HCV therapy should be preceded by the initiation of antiretro-viral therapy[AIII].

Patients with indication for anti-HBV therapy - In patients with indications for treatment of chronic hepatitis B, starting antiretroviral therapy is recommended independently of the CD4+ count and of the other parameters, administering tenofovir in combination with lamivudine or emtricitabine and a third drug or, alternatively, tenofovir with another nucleoside active on HBV (telbivudine or entecavir) in addition to another two antiretrovirals [AII].

 TABLE 26 - Antiretroviral therapy in HIV-infected individuals with coinfections with viral infections (HBV and HCV).

	Coinfection with HCV	Coinfection with HBV	Cirrhosis	
TDM	-	-	Use in patients with decom- pensated cirrhosis	
When to start	Recom	nmended at a CD4 level <500 ce	ell/mm ³	
What to start with (NRTI backbone)	Avoid didanosine and stavu- dine; abacavir only after HLA-B*5701; avoid zidovudi- ne if the patient is candidate to Peg-IFN+RBVUse tenofovir+XTC; do not 			
What to start to (third drug)	Avoid tipranavir and full-dose ritonavir; use nevirapine only as alternative			
Use NNRTI or PI or Integrase inhibitor with a low impact on insulin resistance No other indications Saquinavir not indi decompensated cirrh just dosing in Chi classification of Clas TDM if Child-Pugh cation of Class C				
Management of first failure and successive or alternative treatment strategies	-	Do not discontinue anti-HBV drugs if staging is >F2 accor- ding with METAVIR	-	
*Caution and monitoring of side effects in the case of hepatic impairment (Child-Pugh >7 points) when efavirenz, lopinavir/r, raltegravir, maraviroc are used; in patients with severe hepatic impairment increasing levels of plasma concentration of efavirenz and maraviroc have been observed [BIII]. Use atazanavir at dosing of 300 mg daily (without ritonavir) in patients with cirrhosis and Child-Pugh score between 7 and 9 [BII]. In adults with mild hepatic impairment				

at dosing of 300 mg daily (without ritonavir) in patients with cirrhosis and Child-Pugh score between 7 and 9 [BII]. In adults with mild hepatic impairment (Child-Pugh score 5-6 points) the recommended dosing of fosamprenavir is 700 mg BID with ritonavir 100 mg daily [BII]. In adults with moderate hepatic impairment (Child-Pugh score 7-9 points) the recommended dosing of fosamprenavir is 450 mg BID with ritonavir 100 mg daily

FIGURE 3 - Management of liver toxicity in HIV-infected individuals treated with antiretrovirals.

Tuberculosis

The critical passages regarding the use of combination antiretroviral therapy (cART) in subjects with tuberculosis are:

- Optimal timing of cART initiation with respect to the tuberculosis treatment.
- The selection of antiretroviral drugs to be ad-

ministered with the tuberculosis therapy on the basis of assessment of potential pharmacokinetic interactions and possible cumulative toxicity.

- The risk of developing an immune reconstitution (inflammatory) syndrome (IRIS) after initiation of cART and its management.

	Recommendations	Comments
When to start	Strongly recommended to start cART within three months from the initiation of tuberculosis therapy, independently from CD4 count or plasma HIV-RNA levels	 In patients with CD4 <350 cell/mm3, is recommended to start cART as soon as possible after 2 weeks from the initiation of tuberculosis treatment, in order to evaluate potential adverse reactions to the tuberculosis drugs. In patients with CD4 between 350 and 500 cell/mm3, an early starting of cART is recommended (between 2 weeks and 2 months from the initiation of tuberculosis treatment) In patients with CD4 >500 cell/mm3, the optimal timing of cART initiation should be evaluated in the single case, on the basis of cost-effectiveness assessment.
What to start with	Use EFV+2NRTI as choice regimen to be combined with a rifampin-based tuberculosis regimen[BI]	The use of PI/r or PI, combined with rifampin is not indicated. Using PI/r or PI (except for unboo- sted saquinavir) is feasible if combined with rifa- butine [BII]. All these combinations should be used in patients with resistance to NNRTIs or in the ca- se in which NNRTIs are not tolerated.
Immune reconstitution syndrome (IRIS) after cART initiation	Delaying cART initiation after the first months from starting tuberculosis treatment, the incidence and severity of IRIS could be reduced. This strategy is not recommended in patients with CD4 <350 cell/mm ³ [AI]. Do not discontinue cART in case of IRIS [AII]	

TABLE 27 - Principles of ARV management in HIV-infected patients with tuberculosis.

Opportunistic Infections

TABLE 28 - Initiation of antiretroviral therapyduring acute opportunistic infection.

Elements which must be considered include the degree of immuno-suppression, the availability of effective therapy for O.I.S, pharmacological interactions and cumulative toxicity, and the risk of iris In the absence of obvious contraindications, early initia-

In the absence of obvious contraindications, early initiation of ART in the initial phases of an acute O.I.

Immediate initiation of ART is highly recommended in patients with opportunistic infections for which efficacious specific therapies are lacking, such as cryptosporidiosis, microsporidiosis, progressive multifocal leukoencephalopathy (PML), localized cutaneous and mucosal Kaposi sarcoma (KS), multi-resistant herpes simplex infection.

In patients with PCP initiation of ART is highly recommended within 2 weeks of the diagnosis of PCP.

In O.I.s in which the risk of IRIS is higher (tuberculosis, cryptococcal meningitis, atypical micobacterial infections, CMV infection), delayed initiation of ART may be considered.

TABLE 29 - Management of opportunistic infectionsduring antiretroviral therapy.

Opportunistic Infections	Considerations
<12 weeks of ART	 Administer anti-O.I. the- rapy Continue ART [AIII] Consider IRIS
>12 weeks of ART with vi- rological suppression and immunological recovery	 Administer anti-O.I. the- rapy Continue ART [AIII] Consider IRIS Assess whether to modify or intensify ART in case of sub- optimal recovery of CD4+ lymphocytes [CIII]
>12 weeks of ART with virological failure	 Perform resistance test [AI] Administer anti-O.I. the- rapy Modify ART [AI]

ANTIRETROVIRAL THERAPY IN PREGNANCY

General aspects of antiretroviral treatment during pregnancy

Many aspects of antiretroviral therapy in pregnancy are as yet unclear due to the difficulty of conducting randomized clinical studies in this setting and the difficulty of responding to particular clinical questions through controlled clinical or observational studies. In particular, there is no evidence to guide: the optimal timing antiretroviral treatment initiation in pregnancy for women who have no other indication for the treatment, which choice of drugs and regimens is safe to continue during the pregnancy, and what is the long-term impact of antiretroviral therapy during pregnancy on survival.

Approach to antiretroviral therapy in pregnancy

The recommended therapeutic approach is based on the combined administration of ante partum and intra partum maternal therapy and on antiretroviral prophylaxis in the newborn. This therapeutic schema should be applied to all pregnant women with HIV, independent of the CD4 and HIV-RNA values. Where, due to late access to treatment, the ante partum or intra partum therapy cannot be delivered, administration of the remaining components of the therapeutic schema is fundamental.

It is necessary to consider separately women with maternal indications for antiretroviral therapy and those whose sole indication is the prevention of vertical transmission.

Principal therapeutic scenarios

Pregnant women with maternal indication for antiretroviral treatment must receive a combination regimen of potency analogous to that recommended in non-pregnant women. If the woman is not yet undergoing treatment and there is indication for immediate treatment, it must be initiated as soon as possible. For women with no indication for antiretroviral therapy, the general recommendation is to administer, in all cases, a potent combination regimen, as combination regimens have been found to be the most effective in preventing vertical transmission. Independent of the individual indication for antiretroviral therapy in pregnancy (presence or otherwise of the maternal indication for treatment in addition to prevention of vertical transmission), the use of antiretroviral mono-therapy in pregnancy should be considered inadequate due to its suboptimal antiviral efficacy, the higher risk of development of resistance, and the greater efficacy of the combined therapy in preventing vertical transmission.

Pregnancy is characterized by significant physiological changes operating at different levels on absorption, distribution, metabolism and elimination of drugs. Reduced plasma levels of drugs in pregnancy have been reported by diverse authors, especially in the third trimester, most frequently protease inhibitors, which show greater variability than NRTI and NNRTI.

Monitoring plasmatic drug levels

In general, plasmatic drug level monitoring is not recommended (TDM) in all pregnant women with HIV undergoing treatment, but should be considered in particular situations (e.g.: pathologies or concomitant treatments which can significantly interfere with the metabolism, drugs or regimens particularly those for which there is no available data during pregnancy, toxicity or inefficacy of unclear cause, need to precisely define the levels relative to the presence of resistance, etc.). For the management of these problems, increasingly interesting and growing in complexity, please refer to the specific section dedicated to Pharmacological Monitoring and Interactions.

Virological monitoring during pregnancy: viral load and resistance

Virological objectives of antiretroviral treatment in pregnancy

Viral load monitoring in pregnancy is of particular relevance as the maternal viral load is an independent determinant of vertical transmission.

It is thus particularly important to maintain the viral load undetectable in women at the beginning of the pregnancy and to achieve viral suppression of HIV as rapidly as possible to undetectable levels in women commencing treatment during pregnancy. Viral load monitoring may be performed every two-three months in women on stable therapy and with undetectable HIV at baseline, while in women commencing treatment or requiring modification during pregnancy closer monitoring of response to treatment is advised.

An HIV-RNA assessment is recommended in all women at about week 34-36 of gestation.

Therapeutic failure

In the presence of therapeutic or virological failure, it is necessary to rapidly modify the treatment in order to guarantee the lowest possible levels of viral load at the time of delivery. To his end, a resistance test to guide the choice of treatment is highly recommended.

Performance of resistance testing

The use of the resistance assay during pregnancy, follows the general directives regarding adults a resistance test is recommended in all women not yet on treatment and in all those undergoing treatment with a confirmed detectable RNA. The test must be ordered in a timely manner, and optimal period for delineation of resistances and choice the treatment in pregnancy is the pre-conception period.

Antiretroviral therapy in women already undergoing treatment at conception

Ideally, the regimen at conception should have been selected in the pre-conception period according to criteria which assure safe usage in pregnancy, so that modification or interruption is not required in the early weeks of gestation.

In prescribing potentially teratogen drugs (e.g. efavirenz) to women of reproductive age or other regimens or drugs characterised by additional risk of toxicity in pregnancy (e.g. lactic acidosis, hepatotoxicity, diabetes), it is necessary to consider the possibility of an unplanned pregnancy and individually assess the risk/benefit of treatment relative to the risk of unplanned pregnancy.

In women undergoing antiretroviral treatment with unplanned pregnancy, the regimen must be re-assessed as soon as possible in order to determine its safety for use in pregnancy.

Antiretroviral treatment in women who have never received antiretrovirals prior to pregnancy

137

Choice of the treatment regimen

Where there is a maternal indication for treatment, it must commence as soon as possible, also in the first trimester, using a potent regime of a combination of drugs which has the best evidence for safety in pregnancy.

Where the indication for treatment is solely for prophylaxis of vertical transmission, it is possible to consider and discuss with the patient initiation of treatment after the first trimester, but it is necessary to consider that in the absence of treatment there is a risk of *ante partum* transmission.

Timing of starting treatment

It is not possible to recommend, on the basis of the available evidence, an optimal timing for starting of the antiretroviral treatment in pregnancy for women with no personal indication for treatment [9], but the trimester for initiation of the treatment must guarantee a therapy duration sufficient to achieve complete viral suppression in the final phases of the pregnancy, also considering the possibility that the duration of the pregnancy may be reduced by the risk of pre-term birth.

Potency of the regimen

In all women, including those with no personal indication for treatment, the potency of the regime must be adequate to achieve complete viral suppression, and in general, combination regimens must used at the same potency of those recommended for the treatment of all adults. In the case of women with viral loads below 1000 copies/mL in the absence of treatment, controversy remains as to whether regimens of lesser potency than those used for treatment of adults are to be recommended.

Interruption of treatment

In the case of interruption of antiretroviral treatment during pregnancy, treatment interruption must be immediate and simultaneous for all drugs in cases of severe and life threatening toxicity or grave hyperemesis. In case of elective interruption, in order to prevent the selection of re-

sistant strains, if agents with a long half-life are part of the regimen (e.g. NNRTI, non nucleoside analogues), it is strongly recommended the sequential discontinuation of drugs with long half lives first, with continued administration of other regimen components for a period of time sufficient to guarantee triple antiretroviral coverage as NNRTI levels diminish.

Continued administration of the other drugs for at least 7 days may be considered sufficient, but there is notable variability in the time at which the NNRTIs become undetectable in plasma after discontinuation.

Recent Italian data, while limited to a number of vertical transmission cases and not exclusively involving HAART therapies but including monotherapy (10.6%) and dual therapy (20.0%), suggest that interruptions of treatment in pregnancy may constitute a significant risk factor for mother-to-child HIV transmission.

POST-EXPOSURE PROPHYLAXIS

Indications for post-exposure prophylaxis

- PEP must be initiated as soon as possible after exposure, preferably within 1-4 hours, and no later than 48 hours [AII].
- Exposed subjects who have initiated PEP must

be evaluated by an expert within 48-72 hours of treatment initiation [AIII].

- In those cases where the serostatus of the source patient is unknown and the source patient is available, an targeted epidemiological investigation should be conduced and a sero-logical test performed, once consent has been obtained; the result must be rapidly available, and where available rapid tests should be used[AIII].
- Where serological testing is not possible in the time available, commencement of treatment is recommended with a new visit planned to reevaluate transmission risk, once source-patient test results have been obtained [AIII].
- An exposure source patient who refuses consent to testing must be considered HIV-infected [AIII].
- Tests based on detection of antigens and antibodies are preferable. Use to bio-molecular techniques is not indicated for the purpose of ascertainment of infection [AII].
- Performance of ad hoc tests to determine resistance to the ARVs is not recommended [AIII].
- During initial counseling of the exposed subject, the risks connected with the specific exposure must be explained in order to facilitate correct perception of the probability of infection and facilitate decision-making on PEP uptake (*Tables 1* and 2) [AIII].

a) OCCUPATIONAL EXPOSURE			
Exposure Mode	Source Patient		
	HIV+* or HIV negative but with history or current pathology indica- tive of very recent at risk exposure (e.g. acute viral hepati- tis, IST, endocarditis of right heart) or refusing to consent to serology tests for HIV		
Conjunctival contamination with blood or CSF Exposure to material with elevated viral concentration (e.g. cultures, concentrated suspensions of virus) in any modality.	HIV+*		
*The risk is significantly reduced if the source is on ARV therapy with consistently undetectable viral loads in recent months. In situations other than those indicated, PEP may be considered by an expert on the basis of careful assessment of the risk taking into account the efficiency			

TABLE 30 - Recommendations for offering PEP.

In situations other than those indicated, PEP may be considered by an expert on the basis of careful assessment of the risk taking into account the efficiency of transmission connected with the exposure modality and the contagiousness of the source.

al violence				
al violence				
logical state of the source				

In situations other than those indicated, PEP may be considered by an expert on the basis of careful assessment of the risk taking into account the efficiency of transmission connected with the exposure modality and the contagiousness of the source.

Prophylaxis regimes

- PEP must be composed of a three drug combination regime [AIII].
- PEP must be continued for 28 days [AIII].
- In the case of an HIV positive source, the choice of drugs must be guided by the resistance profile by genotyping, if available, or from the chart review [AII].
- The medical history of the exposed and eventual interactions with other drugs must be considered in the choice of the drugs [AIII].
- Any combination of ARV drugs approved for the treatment of patients with HIV infection may be used for PEP, with the same con-

traindications, including new drugs which become available in the future [AIII].

- At this time nevirapine is the sole drug whose use is not recommended, in the presence of alternatives, due to severe toxicity in immune competent subjects. The use of stavudine and of abacavir should be reserved solely for those cases without valid alternatives, due to possible serious reactions [AII].
- Pregnancy is not an absolute criterion for exclusion from PEP; the use of efavirenz is not recommended (possible teratogenicity), stavudine and didanosine (lactic acidosis), indinavir (hyperbilirubinaemia as birth approaches) [AII].
