## Chapter 5

## Asymmetric Aryl Transfer to Imines: Synthesis of Diarylmethylamines

### 5.1. Introduction

As specified in Chapter 4, control of the stereochemistry in the formation of chiral diarylmethanols has attracted considerable interest over the past 20 years.

Enantiopure diarylmethylamines are also important intermediates for the synthesis of biologically active compounds. As a consequence, many efforts have been made for the synthesis of these molecules.

Several routes allow access to these compounds (scheme below): i) carbon-carbon bond formation of aromatic arylimines and the appropriate organometallic compounds (path A); ii) nucleophilic displacement at the benzylic position (path B); iii) or reduction of $\mathrm{C}=\mathrm{N}$ bond of the corresponding diarylketimines (path $\mathbf{C}$ ).

In the case of diarylmethylamines efficient catalytic asymmetric reductions of the corresponding diarylimines are still lacking and only the enantioselective aryl transfer reaction to aldimines has been developed. This usually involves chiral rhodium complexes, or, alternatively, is catalysed by chirally modified lithium or zinc reagents:

Addition to aldimines

An example of a diarylmethylamine which is precursor for a compound with physiologically interesting properties is the second-generation histamine $\mathrm{H}_{1}$ antagonist cetirizine hydrochloride $\left(\right.$ Zyrtec $\left.^{\circledR}\right)$. Significantly, only the $(S)$-enantiomer of the this compound is biologically active (5.1), and it has therefore been marketed in enantiopure form since the beginning of 2002 (Levocetirizine Xyzall ${ }^{\text {® }}$ ).

5.1

The first catalysed asymmetric aryl transfer reaction onto imines, resulting in the formation of optically active diarylmethylamines with high enantiomeric excesses, was reported by Hayashi in 2000. ${ }^{1} N$-Arylsulfonylimines served as substrates in a rhodium(I)-catalysed process with arylstannanes as aryl source. Monodentate phosphines $(R)$-MeO-MOP 5.2 or $(R)$-Ar*-MOP $\mathbf{5 . 3}$ were the most effective ligands.

The substituent in the para-position of the sulfonyl arene $\left(\mathrm{Ar}^{2}\right)$ determined the reactivity of the aryl-accepting imines. The presence of more electron-withdrawing substituent (for example a $\mathrm{NO}_{2}$ group) led to higher enantiomeric excesses and better yields of the resulting diarylmethylsulfonamides. Also the aromatic substituent ( $\mathrm{Ar}^{1}$ ) of the imine played an important role: the aryl transfer onto electron poor imines $\left(\mathrm{Ar}^{1}=p-\mathrm{F}_{3} \mathrm{CPh}, p-\right.$
$\mathrm{MeO}_{2} \mathrm{CPh}, p-\mathrm{ClPh}$ and $p$ - FPh ) furnished the products with excellent enantioselectivities ( $\geq 96 \%$ ) in very high yields ( $\geq 90 \%$ ). In contrast the unsubstituted imine, derived from benzaldehyde (with $\mathrm{Ar}^{1}=\mathrm{Ph}$ ), gave the products with (only) up to $92 \% e e$ in $86 \%$ yield. Also, the type of phosphine ligand was crucial in this reaction. When chelating bisphosphine such as BINAP and DIOP were used, the reaction was very slow and the product could at best be isolated in only $10 \%$ yield with up to $6 \%$ ee Compared to catalyses with rhodium complexes bearing $\mathrm{MeO}-\mathrm{MOP}$ as ligand, improved enantioselectivities and higher yields were achieved in reactions with the slightly modified phosphine like Ar*-MOP. Synthetically important is the fact that products with N -nosyl groups $\left(\mathrm{SO}_{2} \mathrm{Ar}^{2}=\mathrm{Ns}\right)$ easily afforded primary amines in good yields upon removal of the protecting group by reaction with benzenethiol and $\mathrm{K}_{2} \mathrm{CO}_{3}$ in DMF.

An alternative approach to asymmetric phenyl transfer reactions onto imines was described by Bolm and Bräse in 2002. ${ }^{2}$ There, in situ formed N-formylimines accepted aryl groups from mixtures of diphenyl- and diethylzinc. After screening several catalysts based on ferrocene, cyrhetrene and other N,O-chelates having [2.2]paracyclophane backbones, $\mathbf{5 . 4}$ was identified as the most effective catalyst for this reaction. The substrates, N -formylimines, were formed in situ by deprotonation of amides and subsequent elimination of the sulfinate.

The best result was obtained with $p$-tolylamide amide (with $\mathrm{R}=4-\mathrm{Me}$ ) in combination with $10 \mathrm{~mol} \%$ of $\mathbf{5 . 4}$ in toluene at $-20^{\circ} \mathrm{C}$, which led to the product with $97 \%$ ee in $98 \%$ yield. Various electronic and steric modifications of the aryl acceptors were tolerated.

Compounds with electron rich, electron poor and bulky substituents on the aromatic ring gave excellent results with enantioselectivities up to $95 \%$ ee. However, metasubstituted substrates resulted in slightly lower enantiomeric excesses.

In 2004, Hayashi demonstrated rhodium-catalysed diaryl-methylamine formations with titanium reagents as aryl sources. ${ }^{3}$ There, complexes with Segphos $\mathbf{5 . 5}$ as ligand were applied, and $N$-Arylsulfonylimines with $\mathrm{Ar}^{1}=\mathrm{Ph}$ and aryltitaniumtriisopropoxides with $\mathrm{Ar}^{3}=4-\mathrm{Ph}$ served as starting materials.

5.5

The latter are highly reactive towards transmetalation and form aryl rhodium species, which are capable of transferring the aryl group to the imine in an enantioselective fashion. Sterically demanding sulfonylaryl groups having three isopropyl substituents on the aromatic ring were essential for achieving high enantioselectivities. A wide range of neutral, electron rich and electron poor imines as well as a variety of titanium reagents proved applicable.

Recently, asymmetric addition of aryllithium reagents to aromatic imines in the presence of $\mathrm{C}_{2}$-symmetric diamines such as $\mathbf{5 . 6}$ and $\mathbf{5 . 7}$ have been described. ${ }^{4}$ Although in some cases an excess of the ligands was required, their amount could often be reduced to substoichiometric quantities ( $20 \% \mathrm{~mol}$ ) without significant loss of enantioselectivity. Several diamines were tested and products with up to $84 \%$ ee (at
$19 \%$ conversion) were obtained using $20 \% \mathrm{~mol}$ of $N, N, N^{\prime}, N^{\prime}$-tetramethylcyclohexyl-1,2-diamine (with $\mathrm{R}=\mathrm{H}$ ) in toluene at $-78^{\circ} \mathrm{C}$.

5.6

5.7

In 2004, Tomioka reported the catalytic asymmetric aryl transfer reaction onto N tosylarylimines (with $\mathrm{SO}_{2} \mathrm{Ar}^{2}=\mathrm{Ts}$ ) with arylboroxines as aryl sources. ${ }^{5}$ The reaction was catalysed by a rhodium(I) complex bearing the L-valine-derived amidomonophosphane as chiral ligand 5.8.

5.8

5.9: $\mathrm{R}=3-\mathrm{Cl}$
5.10: $\mathrm{R}=4-\mathrm{OMe}$

The enantiomeric excesses of the resulting tosylamines were found to be dependent on the substitution pattern of $\mathrm{Ar}^{1}$. The best result ( $94 \% \mathrm{ee}, 99 \%$ yield) was achieved in the formation of amine 5.9. In this catalysis, trimethylsilyl-substituted arylimine served as starting material, which reacted with $m$-chlorophenylboroxine in $n$-propanol at $60^{\circ} \mathrm{C}$.

Also, an electron rich boroxine $\left[(p-\mathrm{MeOPhBO})_{3}\right]$ was successfully applied in this addition reaction forming $\mathbf{5 . 1 0}$ in $90 \%$ ee and $\mathbf{8 7 \%}$ yield.

Recently, a rhodium-catalysed, asymmetric addition reaction of arylboronic acids to N diphenylphosphinoyl aldimines was described by Ellman. ${ }^{6}$ This study also included a diastereoselective variant of this reaction using a chiral auxiliary. After screening several diphosphines, ( $R, R$ )-DeguPHOS 5.11 was found to be the most effective ligand, giving phosphinic amides with up to $96 \%$ ee in high yield.

$5.11=(R, R)$-DeguPHOS

Interestingly, acceptable conversions of the imine were only observed with diphosphine ligands having a two-atom spacer between the two diphenylphosphino substituents or a binaphthyl backbone. Other ligands such as Josiphos, Walphos and DIOP gave very low conversions.

Another example is the phosphine-free rhodium catalysis reported by Hayashi in $2004 .{ }^{7}$ With $\mathrm{C}_{2}$-symmetric bicyclo-[2.2.2]octadienes (bod*) or bicycle [2.2.1]heptadiene (Bnnbd*) 5.13 as ligands, the asymmetric aryl transfer reaction between N -tosylarylimines and aryl boroxines proceeded smoothly within 6 h at $60^{\circ} \mathrm{C}$. The catalyst was generated from $\left[\mathrm{RhCl}\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}\right]_{2}(3 \mathrm{~mol} \%$ of Rh$)$, aqueous $\mathrm{KOH}(20 \mathrm{~mol} \%)$ and the chiral diene ( 3 $\mathrm{mol} \%$ ) in dioxane. Using $p$-chlorophenylboroxine (with $\mathrm{Ar}=4-\mathrm{ClPh}$ ) as the aryl source and N -tosylphenylimine as aryl acceptor, the rhodium catalyst generated from Ph-bod* 5.12 led to the corresponding amine with excellent $e e(99 \%)$ in very high yield (99\%).

## L* $=$ Ph-bod* <br> 5.12

L* = Bn-nbd*
5.13

In subsequent studies, Hayashi described the use of 2,6-diphenylbicyclo[3.3.1]nona-2,6diene ( Ph -bnd*) $\mathbf{5 . 1 4}$ and 2,6-diphenylbicyclo[3.3.2]deca-2,6-diene ( $\mathrm{Ph}-\mathrm{bdd} *) \mathbf{5 . 1 5}$ in this rhodium-catalysed aryl transfer reaction.

$\mathbf{L}^{*}=\mathbf{P h}-$ bnd ${ }^{*}$
5.14

$\mathbf{L}^{*}=\mathbf{P h}-\mathrm{bdd}$ *
5.15
$N$-Nosyl-protected arylimines (with $\mathrm{Ar}^{2}=\mathrm{C}_{6} \mathrm{H}_{4}\left(\mathrm{NO}_{2}\right)$ ) could also be applied, giving the corresponding products with up to $99 \% e e$ in almost quantitative yield. The catalyst with Ph-bnd* 5.14 as ligand showed the highest enantioselectivity for both nosyl and tosyl protected imines. In general, all rhodium complexes with diene ligands showed higher activities than those bearing phosphine as ligands.

More recently, monodentate phosphite ligands have been used by Zhou and coworkers in the highly enantioselective ( $e e^{\prime}$ 's $85-96 \%$ ) addition of arylboronic acids to N tosylarylimines, ${ }^{8}$ while the group of de Vries, Feringa and Minnaard reported good enantioselectivities (ee's 82-94\%) in the rhodium-catalyzed arylation of $\mathrm{N}, \mathrm{N}$ dimethylsulfamoylarylimines, using monodentate phosphoramidite ligands.
The group of Zhou obtained the best result with $N$-tosyl-1-naphthaldehyde imine $\left(\mathrm{Ar}^{1}=\right.$ 1-naphthyl) and using the spiro-phosphite $\mathbf{5 . 1 6}$ reported in the scheme below:

The group of Minaard and Feringa got the best enantioselectivities with parachlorobenzaldimine $\left(\mathrm{Ar}^{1}=4-\mathrm{ClC}_{6} \mathrm{H}_{4}\right)$ and using the phosphoramidite 5.17.

$$

### 5.2. Enantioselective rhodium-catalysed addition of arylboronic acids to $N$ tosylarylimines

A library of chiral biphenolic and binaphtholic phosphites and phosphoramidites was initially screened in the Rh-catalyzed addition of phenylboronic acid to $N$-tosyl-ptolylaldehyde imine, using the conditions reported by Zhou and co-workers:

As discussed in Chapter 4, Zhou reported his results about the arylation of N tosylarylimines using the same conditions and ligands tested on aldehydes obtaining a more efficient catalytic system and higher values of ee (up to $96 \%$ ).

The ligands tested by our group and the results obtained are reported in the tables below (the ligands were tested either individually or as binary combinations $\left(\mathrm{L}_{\mathrm{a}} / \mathrm{L}_{\mathrm{b}} 1: 1,3\right.$ mol\% each):

| 14 | $\mathbf{3 . 5 0}$ | 25 | $96(S)$ |
| 15 | $\mathbf{3 . 4 7}$ | 87 | $26(R)$ |

In general, biphenolic phosphites are not selective and sometimes are completely not active as ligands (entries 1-6). Biphenolic phosphoramidites were more selective than phosphites and ligand $\mathbf{3 . 4 3}$ afforded the product with $80 \%$ ee (entries 7-9).
Good enantiomeric excesses were obtained with binaphtholic phosphoramidite ligands containing a bulky chiral amine (i.e. ligands $\mathbf{3 . 4 8}$ and $\mathbf{3 . 5 0}$; entries 12 and 14). Unfortunately, the yields were only moderate for most of the ligands, especially for those which showed the higher selectivity (good yields were obtained with the binaphtholic phosphite $\mathbf{3 . 4 4}$ and Monophos ${ }^{\circledR}$ entries 10, 11 and 15).

In addition, several ligand combinations were screened to investigate the presence of possible cooperative effects.

| Entry | $\mathrm{L}_{\mathrm{a}}$ | $\mathrm{L}_{\mathrm{b}}$ | Yield (\%) | $e e(\%)$ |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |
| 1 | $\mathbf{3 . 4 4}$ | $\mathbf{3 . 4 8}$ | 17 | $49(S)$ |
| 2 | $\mathbf{3 . 4 4}$ | $\mathbf{3 . 4 6}$ | 95 | $50(S)$ |
| 3 | $\mathbf{3 . 4 4}$ | $\mathbf{3 . 4 9}$ | - | - |
| 4 | $\mathbf{3 . 4 8}$ | $\mathbf{3 . 2 7}$ | 50 | $61(S)$ |
| 5 | $\mathbf{3 . 4 4}$ | $\mathbf{3 . 3 8}$ | 56 | $2(R)$ |
| 6 | $\mathbf{3 . 4 6}$ | $\mathbf{3 . 4 3}$ | 55 | $24(S)$ |

When binaphtholic phosphite $\mathbf{3 . 4 4}$ [yield $=87 \%$, $e e=40 \%(S)$ ] and Monophos ${ }^{\circledR} 3.46$ [yield $=90 \%, e e=27 \%(S)$ ] were used in combination, a small cooperative effect was observed [yield $=95 \%$, ee $=50 \%(S)$; entry 2]. Although the increase of $e e$ obtained by the combination of these two ligands is only marginal and not synthetically useful, it implies that both ligands are present in the rhodium complex during the enantiodiscriminating step of the reaction.

Encouraged by the $e e$ 's obtained with ligands $\mathbf{3 . 4 8}$ and $\mathbf{3 . 5 0}$, we decided to screen different reaction conditions (solvent, base and temperature) using ligand $\mathbf{3 . 4 8}$ (more easy to be synthesized), in order to improve the yields of the reaction.

| Entry | Solvent | Base (eq) | $\mathrm{PhB}(\mathrm{OH})_{2}$ | Temp <br> $\left({ }^{\circ} \mathrm{C}\right)$ | Yield (\%) | $e e(\%)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| $\mathbf{1 2}$ | dioxane | $\mathrm{LiF} \mathrm{(10)}$ | $\mathbf{5}$ equiv. | $\mathbf{5 0}$ | $\mathbf{7 8}$ | $\mathbf{8 7}$ |

While no improvement was observed using numerous solvent-base combinations [dry toluene, acetone, THF/ $\mathrm{H}_{2} \mathrm{O}(1: 1)$, dioxane $/ \mathrm{H}_{2} \mathrm{O}(10: 1)$, dioxane $/ \mathrm{H}_{2} \mathrm{O}$ (1:2) as solvents, with $\mathrm{LiF}, \mathrm{KF}, \mathrm{KOH}, \mathrm{Et}_{3} \mathrm{~N}$ as bases], good yields and ee's were finally obtained using anhydrous dioxane with LiF as base (entry 12 ). ${ }^{9}$

The new reaction conditions are summarized in the scheme below:

A small sub-library of phosphoramidite ligands (figure below) was then tested under these optimized conditions in the addition of phenylboronic acid to $N$-tosyl- $p$ tolylaldehyde imine. Since the presence of a bulky amine derivative was apparently necessary to obtain a high $e e$, we decided to include 3.50, the two ligands $\mathbf{3 . 4 9}$ (distereomer of $\mathbf{3 . 4 8}$ ) and $\mathbf{3 . 5 1}$ (the diastereomer of $\mathbf{3 . 5 0}$ ), the biphenolic ligand $\mathbf{3 . 4 3}$ to test the effective role of the amine moiety in this reaction and, finally, the binaphtholic phosphoramidite $\mathbf{3 . 5 2}$ derived from bis(1-naphthylethyl)amine (see the table below)

3.50
3.43

| Entry | L $^{*}$ | Yield (\%) | $e e(\%)$ |
| :---: | :---: | :---: | :---: |
|  |  |  |  |
| 1 | $\mathbf{3 . 4 8}$ | 60 | $87(S)$ |
| 2 | $\mathbf{3 . 4 9}$ | 21 | $33(R)$ |
| 3 | $\mathbf{3 . 5 0}$ | 93 | $90(S)$ |
| 4 | $\mathbf{3 . 4 8}$ | 82 | $86(S)$ |
| 5 | $\mathbf{3 . 4 3}$ | 65 | $84(S)$ |
| 6 | $\mathbf{3 . 5 2}$ | 15 | $76(R)$ |

A clear matched combination of the binaphthol chiral axis and of the amine stereocenters is observed for phosphoramidite $3.48\left(S_{a}, S, S\right)$ [yield $=60 \%$, ee $=87 \%(S)$; entry 1] with respect to $\mathbf{3 . 4 9}\left(R_{d}, S, S\right)$ [yield $=21 \%$, ee $=33 \%(R)$; entry 2]. On the contrary, in the case of $\mathbf{3 . 5 0}\left(S_{a}, S, S\right)$ and $\mathbf{3 . 5 1}\left(R_{a}, S, S\right)$, which also share the same enantiomer of the amine moiety, the opposite enantiomer of the binaphthol chiral axis plays only a very marginal role $[e e=90 \%(S)$ vs. $e e=86 \%(S)$, entries 3 and 4]. The importance of the 2,5-diphenylpyrrolidine moiety is further confirmed by the $84 \% \mathrm{ee}$ in favor of the $S$ enantiomer (entry 5) obtained using ligand 3.43, which is devoid of the chiral axis. Ligands $\mathbf{3 . 5 0}$ and $\mathbf{3 . 4 3}$ have already been used by us ${ }^{10,11}$ and others ${ }^{12}$ as very effective ligands in different reaction processes. Ligand $3.52\left(S_{a}, S, S\right),{ }^{13}$ which contains a bulkier amine substituent, showed a reduced yield and a reversed enantiofacial
selectivity [yield $=15 \%$, ee $=76 \%(R)$; entry 6]. This result might indicate that a different mechanism is operating in this case: possibly the active Rh-complex contains only one ligand.

Having established the optimal synthetic protocol, the scope of this arylation reaction was examined, testing several aromatic imines and arylboronic acids, and using our best ligands $\mathbf{3 . 4 8}$ and 3.50:

Moderate to excellent $e e$ 's (51-99\%) were obtained in the arylation of differently substituted $N$-tosylarylimines, containing either electron-donating or electronwithdrawing substutents, while the catalytic efficiency was moderate in most cases, as witnessed by the conversions. An excellent ee (99\%; entry 7) was obtained with N -tosyl-1-naphthaldehyde imine using ligand 3.48, while only a moderate enantioselectivity ( $e e=51 \%$; entry 8 ) was observed with ligand 3.50. Electron-rich substrates gave generally higher yields (entries 1-10), while a slower addition reaction, associated with lower overall yields, occurred with electron-poor substrates (entries 1114). Electron-rich arylboronic acids (entries 15-18) gave generally good yields in the addition to $N$-tosylbenzaldimine, associated with moderate/good $e e$ 's. The steric hindered group 1-naphthyl on the boronic acid didn't afford the product (entries 19-20), and also the electron-poor arylboronic acid $\left(4-\mathrm{Cl}-\mathrm{C}_{6} \mathrm{H}_{4}\right) \mathrm{B}(\mathrm{OH})_{2}$ showed a complete inactivity (entries 21-22) as reported in many papers.

### 5.3. Experimental section

## General procedure for the synthesis of $\boldsymbol{N}$-tosyl arylimines ${ }^{14}$

In a flask flushed with nitrogen p-toluensulfonamide ( $1.1 \mathrm{eq}, 4.2 \mathrm{mmol}, 754 \mathrm{mg}$ ) was suspended in 20 mL of dry $\mathrm{CH}_{2} \mathrm{Cl}_{2}$. The aromatic aldehyde ( $1 \mathrm{eq}, 4 \mathrm{mmol}$ ) was added and finally trifluoroacetic anhydride ( $1.1 \mathrm{eq}, 4.2 \mathrm{mmol}, 620 \mu \mathrm{~L}$ ). The mixture was heated to reflux (it becomes a solution) and stirred at this temperature for 3 days.

The still warm mixture was poured into 60 mL of water, the aqueous phase was extracted twice with $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ and the combined organic extracts washed with brine. The solvent was evaporated affording a solid which was purified by flash chromatography using as eluent a mixture of $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ /petroleum ether.

For the characterization of $N$-tosyl arylimines different literature procedures were followed. ${ }^{15}$

## Phenyl $N$-tosyl imine

$95 \%$ yield; ${ }^{1} \mathrm{H}$ NMR (CDCl3) $\delta 9.03(\mathrm{~s}, 1 \mathrm{H}), 7.87-7.95(\mathrm{~m}, 4 \mathrm{H}), 7.59-7.64(\mathrm{~m}, 1 \mathrm{H})$, 7.46-7.52 (m, 2H), 7.35 (d, $J=7.9 \mathrm{~Hz}, 2 \mathrm{H}), 2.44$ (s, 3H).

## 4-Methylphenyl $N$-tosyl imine

$83 \%$ yield; ${ }^{1} \mathrm{H}$ NMR $(\mathrm{CDCl} 3) \delta 8.98(\mathrm{~s}, 1 \mathrm{H}), 7.86-7.91(\mathrm{~m}, 2 \mathrm{H}), 7.79-7.84(\mathrm{~m}, 2 \mathrm{H})$, 7.31-7.34 (m, 2H), 7.27-7.31 (m, 2H), 2.43 (s, 3H), 2.42 (s, 3H).

## 4-Chlorophenyl $N$-tosyl imine

## 2-Furyl $N$-tosyl imine

$72 \%$ yield; ${ }^{1} \mathrm{H}$ NMR (CDCl3) $\delta 9.08(\mathrm{~s}, 1 \mathrm{H}), 7.86(\mathrm{~m}, 2 \mathrm{H}), 7.74(\mathrm{~m}, 1 \mathrm{H}), 7.34(\mathrm{~m}, 3 \mathrm{H})$, 6.64 (m, 1H), 2.42 ( $\mathrm{s}, 3 \mathrm{H}$ ).

## General procedure for the arylation of $N$-tosyl arylimines ${ }^{9}$

In a flame dried Schlenk tube flushed with nitrogen, $1.2 \mathrm{mg}(4.65 \mu \mathrm{~mol}, 3 \mathrm{~mol} \%)$ of $\mathrm{Rh}(\mathrm{acac})\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)_{2}$ and $9.30 \mu \mathrm{~mol}(6 \mathrm{~mol} \%)$ of the ligand were dissolved in dry dioxane $(0.75 \mathrm{~mL})$. After stirring for 30 min at room temperature, $\mathrm{LiF}(1.5 \mathrm{mmol})$ and the substrate ( 0.15 mmol ) were added followed by the appropriate arylboronic acid ( 0.75 $\mathrm{mmol})$. The resulting mixture was stirred at $50^{\circ} \mathrm{C}$ for 24 h , quenched with water ( 3 mL )
and extracted with $\mathrm{CH}_{2} \mathrm{Cl}_{2}(3 \mathrm{~mL})$. The organic phase was dried over $\mathrm{Na}_{2} \mathrm{SO}_{4}$ and the solvent evaporated under vacuum. The residue was purified by flash chromatography on silica gel with a mixture of $n$-hexane/EtOAc affording the $N$-tosyl-diarylmethylamine as a white solid.

Both the $e e^{\prime}$ 's and the absolute configurations were determined by HPLC using a Chiralcel OD-H or AD-H column. ${ }^{8}$
